**Aim of Study:** To investigate oral health related quality of life (OHRQoL) and denture satisfaction of complete denture patients before and after the provision of two implants to support mandibular overdenture. **Materials and Method:** Nineteen patients were involved in this study. A new set of complete dentures was provided for each patient. After 2 or 3 weeks, patients were reviewed and asked to complete Oral Health Impact Profile Malaysian version (S-OHIP [M]) and denture satisfaction questionnaires. The patients completed the same questionnaires 2-3 months after the implant treatment. Data were analyzed using SPSS. Composite score was computed for the OHIP data, higher score indicated better OHRQoL. *t*-test was used to compare the OHIP score before and after implant treatment. Denture satisfaction was analyzed as percentage. Significance level is set at 0.05. **Results:** The total OHIP score was significantly higher after implant treatment; with significant improvement in the domains of functional limitation, physical pain, psychological discomfort, and physical disability (p<0.05). About 90% of patients reported general denture satisfaction before implant while the percentage slightly increased to 95% after implant treatment. 100% of the patients reported satisfaction with their mandibular implant overdenture in chewing ability and denture comfort. **Conclusion:** Mandibular implant overdenture improves OHRQoL and denture satisfaction.
